Exercise 4 - Variables

[Overview](#)[My Submissions/Test Runs](#)

Instructions

Write a program that switches the values stored in the variables a and b.

Warning. Do not change the code on lines 1-4 and 12-18. Your program should work for different inputs. e.g. any value of a and b.

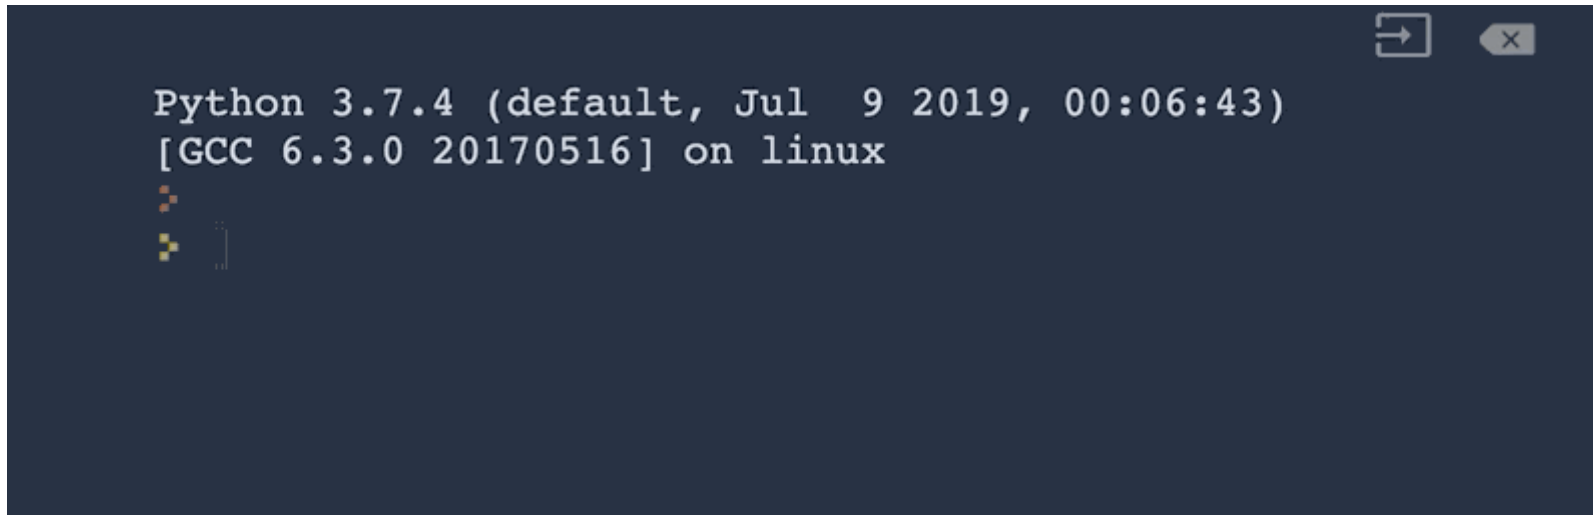

Example Input

```
a: 3  
b: 5
```

Example Output

```
a: 5  
b: 3
```

e.g. When you hit **run**, this is what should happen:

A terminal window with a dark blue background. The text inside shows the Python version and GCC version on a Linux system. There are two small icons in the top right corner: a square with a right-pointing arrow and a grey rectangle with a white 'x'.

Hint

1. You should not have to type any numbers in your code.
2. You might need to make some more variables.

Test Your Code

Check your code is doing what it is supposed to. When you're happy with your code, click submit to check your solution.
