

[< Interactive Coding Exercises](#)

Exercise 1 - Data Types

Overview

My Submissions/Test Runs

Instructions

Write a program that adds the digits in a 2 digit number. e.g. if the input was 35, then the output should be $3 + 5 = 8$

Warning. Do not change the code on lines 1-3. Your program should work for different inputs. e.g. any two-digit number.

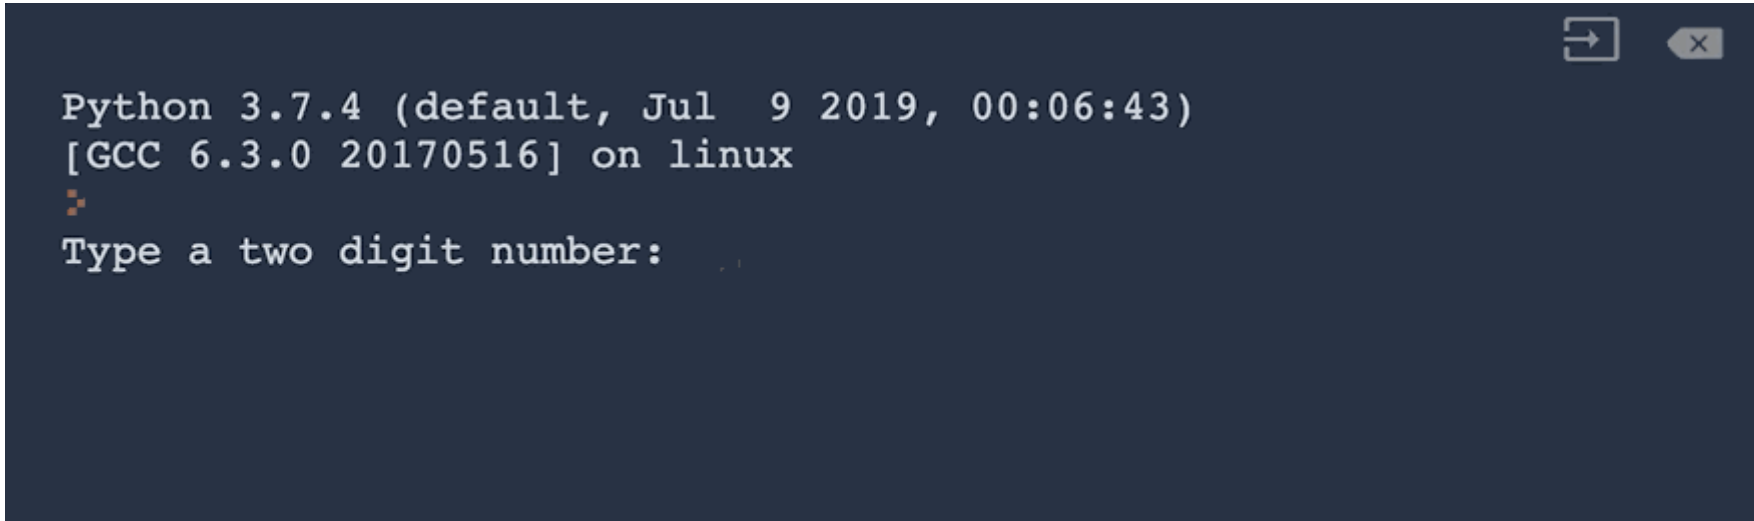

Example Input

39

Example Output

```
3 + 9 = 12
12
```

e.g. When you hit **run**, this is what should happen:

A terminal window with a dark blue background. The text inside is white. It shows the Python 3.7.4 shell prompt, the GCC version and architecture, and a prompt asking for a two-digit number. There are window control icons in the top right corner.

```
Python 3.7.4 (default, Jul  9 2019, 00:06:43)
[GCC 6.3.0 20170516] on linux
Type a two digit number:
```

Hint

1. Try to find out the data type of `two_digit_number`.
2. Think about what you learnt about subscripting.
3. Think about type conversion.

Test Your Code

Check your code is doing what it is supposed to. When you're happy with your code, click submit to check your solution.
